

# Transformation Structures for 2-Group Actions in Higher Gauge Theory

(Joint work with Roger Picken)

Jeffrey C. Morton

SUNY Buffalo State College

Higher Structures in Lisbon, 2017

## Original motivation

Certain TQFT's can be factored as

$$nCob \xrightarrow{F} Span(Gpd) \xrightarrow{D} Vect \quad (1)$$

and may often be promoted to Extended TQFT via

$$nCob_2 \xrightarrow{F} Span_2(Gpd) \xrightarrow{\Lambda} 2Vect \quad (2)$$

The functor  $D$  and 2-functor  $\Lambda$  are Baez-Dolan *degroupoidification* and *2-linearization* respectively, and are general. Different choices of groupoid-valued functors  $F$  for manifolds then give different theories.

The DW model uses  $F = A_0^G$ , which assigns to a manifold  $M$  the groupoid of flat  $G$ -bundles over  $M$ .

## Our Motivating Example

Our original motivation in developing this machinery was to describe the **symmetry** of **moduli spaces** of **connections on gerbes**.

There is a handy fact about connections on bundles:

$$\text{Fun}(\Pi_1(M), G) \cong A_0^G(M) = \text{Conn}(M) // \text{Gauge}(M)$$

where  $\text{Conn}(M)$  is a *moduli space* of connections,  $\text{Gauge}(M)$  is a total group of *gauge transformations* which acts on  $\text{Conn}(M)$ , and we have here the *weak quotient* by this action.

For 1-groups, both of these are groupoids. For 2-groups, the analogous objects are a 2-groupoid and a double-groupoid respectively!

Question: Is there a corresponding equivalence?

## 2-Groups and Crossed Modules

**Idea:** *Categorification of symmetry.* To describe symmetry of categories, generalize group actions.

### Definition

A **2-group**  $\mathcal{G}$  is a 2-category with one object, and all morphisms and 2-morphisms invertible.

A **categorical group** is a group object in **Gpd**: a category  $\mathcal{G}$  with  $\otimes : \mathcal{G} \times \mathcal{G} \rightarrow \mathcal{G}$  and an inverse map satisfying the usual group axioms. In particular, a monoidal category  $(\mathcal{G}, \otimes)$  where every object and morphism is invertible with respect to  $\otimes$ .

I will use “2-group” for both except where the distinction is critical.

2-groups are classified by crossed modules:

### Definition

A crossed module consists of  $(G, H, \triangleright, \partial)$ , where:

- ▶  $G, H \in \mathbf{Grp}$
- ▶  $G \triangleright H$  an action of  $G$  on  $H$  by automorphisms
- ▶  $\partial : H \rightarrow G$  a homomorphism

satisfying

- ▶  $\partial(g \triangleright h) = g\partial(h)g^{-1}$
- ▶  $\partial(h_1) \triangleright h_2 = h_1h_2h_1^{-1}$

A homomorphism of crossed modules is a pair of homomorphisms  $G \rightarrow G'$  and  $H \rightarrow H'$  which is compatible with  $\triangleright$ .

The category of crossed modules and homomorphisms is equivalent to the category of 2-groups under with a correspondence determined by  $\mathbf{G}(G, H, \triangleright, \partial)$  with:

- ▶ **Objects:** elements of  $G$
- ▶ **Morphisms:** elements of the semidirect product  $G \ltimes H$ , with  $(g, h) : g \rightarrow (\partial h)g$  and

$$(\partial(\eta)g, \zeta) \circ (g, \eta) = (g, \zeta\eta).$$

- ▶ **Monoidal Structure:**

$$\begin{array}{|c|c|} \hline g & g' \\ \hline \eta & \eta' \\ \hline \end{array} = \begin{array}{|c|} \hline gg' \\ \hline \eta(g \triangleright \eta') \\ \hline \end{array}$$

$$(\partial\eta)g \quad (\partial\eta')g' \qquad (\partial\eta)g(\partial\eta')g'$$

## Definition

A (strict) action of a 2-group  $\mathcal{G}$  on a category  $\mathbf{C}$  is a functor  $\hat{\Phi} : \mathcal{G} \times \mathbf{C} \rightarrow \mathbf{C}$  (strictly) satisfying the action diagram in  $\mathbf{Cat}$ :

$$\begin{array}{ccc} \mathcal{G} \times \mathcal{G} \times \mathbf{C} & \xrightarrow{\otimes \times Id_{\mathbf{C}}} & \mathcal{G} \times \mathbf{C} \\ \downarrow Id_{\mathcal{G}} \times \hat{\Phi} & & \downarrow \hat{\Phi} \\ \mathcal{G} \times \mathbf{C} & \xrightarrow{\hat{\Phi}} & \mathbf{C} \end{array}$$

Actions of 2-groups make sense in any 2-category, but only take this special form (by *currying*) in  $\mathbf{Cat}$ :

## Lemma

For any  $\mathbf{C} \in \mathbf{Cat}$ , a strict monoidal functor  $\Phi : \mathcal{G} \rightarrow \mathbf{End}(\mathbf{C})$  is equivalent to a strict action  $\hat{\Phi} : \mathcal{G} \times \mathbf{C} \rightarrow \mathbf{C}$ .

## Three Group Actions in a 2-Group Action

If  $\mathcal{G}$  is a 2-group classified by the crossed module  $(G, H, \triangleright, \partial)$ , and  $\hat{\Phi} : \mathcal{G} \times \mathbf{C} \rightarrow \mathbf{C}$  is a strict action, by abuse of notation we denote by  $\blacktriangleright$  three interconnected group actions. Two actions of  $G$  on objects and morphisms of  $\mathbf{C}$ :

- ▶ Given  $\gamma \in \mathcal{G}^{(0)} = G$  and  $x \in \mathbf{C}^{(0)}$ , let

$$\gamma \blacktriangleright x = \Phi_\gamma(x) = \hat{\Phi}(\gamma, x)$$

- ▶ Given  $\gamma \in \mathcal{G}^{(0)} = G$  and  $f \in \mathbf{C}^{(1)}$ , let

$$\gamma \blacktriangleright f = \Phi_\gamma(f) = \hat{\Phi}((\gamma, 1_H), f)$$

(Which are compatible with the structure maps of  $\mathbf{C}$ : source, target, composition, etc.)

One action of  $G \times H$  on morphisms of  $\mathbf{C}$ :

- ▶ Given  $(\gamma, \chi) \in \mathcal{G}^{(1)} = G \times H$  and  $(f : x \rightarrow y) \in \mathbf{C}^{(1)}$ , let

$$\begin{aligned} (\gamma, \chi) \triangleright f &= \hat{\Phi}((\gamma, \chi), f) \\ &= \Phi_{(\gamma, \chi)}(y) \circ (\gamma \triangleright f) \\ &= (\partial(\chi)\gamma \triangleright f) \circ \Phi_{(\gamma, \chi)}(x) \end{aligned}$$

This is the diagonal of the naturality square associated to  $f : x \rightarrow y$  in  $\mathbf{C}$ :

$$\begin{array}{ccc} \gamma \triangleright x & \xrightarrow{\gamma \triangleright f} & \gamma \triangleright y \\ \Phi_{(\gamma, \eta)_x} \downarrow & \dashrightarrow^{(\gamma, \chi) \triangleright f} & \downarrow \Phi_{(\gamma, \eta)_y} \\ (\partial\eta)\gamma \triangleright x & \xrightarrow{(\partial\eta)\gamma \triangleright f} & (\partial\eta)\gamma \triangleright y \end{array}$$

(Note  $\Phi_{(\gamma, \chi)}$  typically assigns a nonidentity morphism to  $x$ , so there is no action of  $G \times H$  on objects of  $\mathbf{C}$ )

## Example: Adjoint Action of $\mathcal{G}$

### Definition (Part 1)

If  $\mathcal{G} \sim (G, H, \triangleright, \partial)$ , then the *adjoint action* of  $\mathcal{G}$  (seen as a 2-group) on  $\mathcal{G}$  (seen as a categorical group) is given by the 2-functor:

- ▶  $\gamma \in \text{Ob}(\mathcal{G})$  gives an endofunctor  $\Phi_\gamma : \mathcal{G} \rightarrow \mathcal{G}$  which itself is defined by:
  - ▶  $\Phi_\gamma(g) = \gamma g \gamma^{-1}$
  - ▶  $\Phi_\gamma(g, \eta) = (\gamma g \gamma^{-1}, \gamma \triangleright \eta)$

Draw this as:

$$\begin{array}{c} g \\ \boxed{\eta} \\ \partial(\eta)g \end{array} \xrightarrow{\Phi_\gamma} \begin{array}{c} \gamma \quad g \quad \gamma^{-1} \\ \boxed{\quad \quad \eta \quad \quad} \\ \gamma \quad \partial(\eta)g \quad \gamma^{-1} \end{array} = \begin{array}{c} \gamma g \gamma^{-1} \\ \boxed{\gamma \triangleright \eta} \\ \gamma \partial(\eta)g \gamma^{-1} \end{array} = \begin{array}{c} \gamma \blacktriangleright g \\ \boxed{\gamma \triangleright \eta} \\ \gamma \blacktriangleright \partial(\eta)g \end{array}$$

## Definition (Part 2)

- ▶  $(\gamma, \chi) \in \text{Mor}(\mathcal{G})$  gives a natural transformation  $\Phi_{(\gamma, \chi)} : \Phi_\gamma \Rightarrow \Phi_{\partial(\chi)\gamma}$ , defined by:

$$\Phi_{(\gamma, \chi)}(g) = (\gamma g \gamma^{-1}, \chi(\gamma g \gamma^{-1}) \triangleright \chi^{-1})$$

Draw this as:

$$\Phi_{(\gamma, \chi)}(g) = \begin{array}{|c|c|c|} \hline \gamma & g & \gamma^{-1} \\ \hline \chi & & \chi^{-1} \\ \hline \partial(\chi)\gamma & g & (\partial(\chi)\gamma)^{-1} \\ \hline \end{array} = \begin{array}{|c|} \hline \gamma \blacktriangleright g \\ \hline \chi(\gamma \blacktriangleright g) \triangleright \chi^{-1} \\ \hline \partial(\chi)\gamma \blacktriangleright g \\ \hline \end{array}$$

# Transformation Groupoids

*Global symmetry* involves actions. *Local symmetry relations* of a set  $X$  is represented as a groupoid (in  $\mathbf{C}$ ) with:

- ▶ Objects: the elements of  $X$
- ▶ Isomorphisms:  $f : x \rightarrow y$  denoting a symmetry relation between  $x$  and  $y$

Any global symmetry action gives a local symmetry groupoid (but not necessarily conversely):

## Definition

The **transformation groupoid** of an action of a group  $G$  on a set  $X$  is the groupoid  $X // G$  with:

- ▶ **Objects:**  $X$  (that is, all  $x \in X$ )
- ▶ **Morphisms:**  $G \times X$ , with  $(g, x) : x \mapsto g \triangleright x$
- ▶ **Composition:** (Multiplication in  $G$ )

# Transformation Double Categories

## Definition

Given a 2-group  $\mathcal{G}$ , a category  $\mathbf{C}$ , and an action of  $\mathcal{G}$  on  $\mathbf{C}$ , the transformation 2-groupoid  $\mathbf{C} // \mathcal{G}$  is the groupoid in  $\mathbf{Cat}$  with:

- ▶  $Ob(\mathbf{C} // \mathcal{G}) = \mathbf{C}$ .
- ▶  $Mor(\mathbf{C} // \mathcal{G}) = \mathcal{G} \times \mathbf{C}$ , with
  - ▶ **Source** functor  $s = \pi_{\mathbf{C}} : \mathcal{G} \times \mathbf{C} \rightarrow \mathbf{C}$
  - ▶ **Target** functor  $t = \hat{\Phi} : \mathcal{G} \times \mathbf{C} \rightarrow \mathbf{C}$
  - ▶ **Composition**: (given by the action condition)

This is really a *double category* - the morphisms of  $Mor(\mathbf{C} // \mathcal{G})$  are squares:

$$\begin{array}{ccc}
 x & \xrightarrow{f} & y \\
 (\gamma, x) \downarrow & ((\gamma, \eta), f) & \downarrow ((\partial\eta)\gamma, y) \\
 \gamma \blacktriangleright x & \xrightarrow{(\gamma, \eta) \blacktriangleright f} & (\partial\eta)\gamma \blacktriangleright y
 \end{array}$$

The squares describe the action of  $G \times H$  on  $Mor(\mathbf{C})$ . They come from diagonals of the cube:

One way to collect all (flat)  $\mathcal{G}$ -connections on gerbes over a manifold  $M$  is as the *2-groupoid* (!) of transport 2-functors:

$$2Fun(\Pi_2(M), \mathcal{G}) \tag{3}$$

where  $\Pi_2(M)$  is the **fundamental 2-groupoid** of  $M$  consisting of

- ▶ **Objects:**  $x \in M$
- ▶ **Morphisms:** Paths  $I \rightarrow M$
- ▶ **2-Morphisms:** Homotopies  $I^2 \rightarrow M$  fixing endpoints (up to homotopy)

Then  $2Fun(\Pi_2(M), \mathcal{G})$  has:

- ▶ **Objects:** 2-functors from  $\Pi_2(M)$  to  $\mathcal{G}$
- ▶ **Morphisms:** Pseudonatural transformations between 2-functors
- ▶ **2-Morphisms:** Modifications

## Definition

A *pseudonatural transformation*  $p : F \Rightarrow G$  between 2-functors assigns data filling the following square:

$$\begin{array}{ccc} F(a) & \xrightarrow{F(f)} & F(b) \\ p_x \downarrow & \Downarrow p_f & \downarrow p_y \\ G(a) & \xrightarrow{G(f)} & G(b) \end{array}$$

compatible with composition and units, and such that for all 2-morphisms  $\alpha : f \rightarrow g$  in  $\mathbf{A}$ , a certain 3D diagram commutes. We say  $p$  is *strict* if all  $p(f) = Id$  (i.e. a “natural transformation”), and *costrict* if for all  $x \in \mathbf{A}$ , we have  $p(x) \equiv Id_{F(x)}$  (thus in particular,  $F(x) = G(x)$ ). (i.e. an “ICON”)

## Lemma

If  $\mathbf{A}$  and  $\mathbf{B}$  are bigroupoids, and  $F, G$  are functors from  $\mathbf{A}$  to  $\mathbf{B}$ , then every pseudonatural transformation  $p : F \Rightarrow G$  is a composite of a strict transformation followed by a costrict transformation. Such  $p$  is also a composite of a costrict transformation followed by a strict transformation:

$$\begin{array}{ccc}
 F(x) \xrightarrow{F(f)} F(y) & = & F(x) \xrightarrow{F(f)} F(y) \\
 \downarrow n(x) \quad \swarrow q \circ 1_{n(x)} \quad \downarrow n(y) & & \downarrow n(x) \quad \quad \quad \downarrow n(y) \\
 G(x) \xrightarrow{G(f)} G(y) & & G'(x) \xrightarrow{G'(f)} G'(y) \\
 & & \parallel \quad \quad \quad \swarrow q(f) \quad \quad \quad \parallel \\
 & & G(x) \xrightarrow{G(f)} G(y)
 \end{array} \tag{4}$$

(And similarly in the reverse order)

## Definition

If  $\mathbf{A}$  and  $\mathbf{B}$  are bicategories, define the double category of 2-functors:

$$\text{Hom}_{\square}(\mathbf{A}, \mathbf{B}) = \text{DbCat}(V(\mathbf{A}), V(\mathbf{B})) \quad (5)$$

If  $\mathbf{A}$  and  $\mathbf{B}$  are bigroupoids, the data of the double groupoid  $\text{Hom}_{\square}(\mathbf{A}, \mathbf{B})$  are in 1-1 correspondence with:

- ▶ **Objects:** Strict 2-functors from  $\mathbf{A}$  to  $\mathbf{B}$
- ▶ **Horizontal Morphisms:** Costrict pseudonatural transformations
- ▶ **Vertical Morphisms:** Strict natural transformations
- ▶ **Squares:** Squares correspond to modifications are modifications  $M : s_2 \circ c_F \Rightarrow c_G \circ s_1$ :

$$\begin{array}{ccc} F_1 & \xrightarrow{c_F} & F_2 \\ s_1 \downarrow & \swarrow M & \downarrow s_2 \\ G_1 & \xrightarrow{c_G} & G_2 \end{array} \quad (6)$$

## Category of Connections

Think of connections on gerbes as determining **holonomies** valued in a 2-group  $\mathcal{G} \sim (G, H, \triangleright, \partial)$  to paths and homotopies of paths in a manifold.

(Note: from fields of Lie-group valued forms, one can get these by integration).

We simplified things by using discrete paths and homotopies made of chosen edges and faces:

Given gauge 2-group  $\mathcal{G}$ , the objects of **Conn** must be connections - which assign  $G$ -holonomies to edges and  $H$ -holonomies to faces:

A Connection on  $(T^2, \mathcal{D})$

Morphisms assign  $H$ -holonomies to edges...

Morphism in  $\mathbf{Conn}(T^2, \mathcal{D})$

Then indeed:

### Theorem

*Given a manifold  $(M)$ , and a strict 2-group  $\mathcal{G}$  presented by the crossed module  $(G, H, \triangleright, \partial)$ , there is an isomorphism:*

$$\mathbf{Conn} // \mathbf{Gauge} \cong \mathit{Hom}_{\square}(\Pi_2(M), \mathcal{G}) \quad (7)$$

Where **Conn** is a category of connections and **Gauge** is a 2-group best understood as  $\mathcal{G}^M$  (or  $\mathcal{G}^V$  in our discrete case, where  $V$  is the set of vertices in a cell structure on  $M$ ).

**Note:** this means that *some local symmetry lives in **Conn** to begin with, and only some comes from the global action.*

Vertical Morphism in **Conn**//**Gauge**( $T^2, \mathcal{D}$ ) (From action of  $G^V$ )

Square - Gauge Modification on  $(T^2, \mathcal{D})$  (from action of  $(G \times H)^V$ )
